SQL Joins and Subqueries

A JOIN combines rows from two tables in a relational database. An inner join keeps only rows that match in both tables, while a left join keeps every row from the first table.

A subquery is a SELECT statement nested inside another SQL query. Subqueries let a query filter records using values computed from another table.

Always join on primary key and foreign key columns so the database can match records efficiently. Selecting only the columns you need keeps each SQL query fast and readable.
